AKRAM ALZAGHIR

Data Wrangling

Estimated time needed: **30** minutes

Objectives

After completing this lab you will be able to:

- Handle missing values
- Correct data format
- Standardize and Normalize Data

Table of content

- Identify and handle missing values
  - Identify missing values
  - Deal with missing values
  - Correct data format
- Data standardization
- Data Normalization (centering/scaling)
- Binning
- Indicator variable

What is the purpose of Data Wrangling?

Data Wrangling is the process of converting data from the initial format to a format that may be better for analysis.

What is the fuel consumption (L/100k) rate for the diesel car?

Import data

You can find the "Automobile Data Set" from the following link: https://archive.ics.uci.edu/ml/machine-learning-databases/autos/imports-85.data (https://archive.ics.uci.edu/ml/machine-learning-databases/autos/imports-85.data). We will be using this data set throughout this course.

Import pandas

In [87]:

```
import pandas as pd
import matplotlib.pylab as plt
```

Reading the data set from the URL and adding the related headers.

URL of the dataset

This dataset was hosted on IBM Cloud object click HERE (https://cocl.us/corsera_da0101en_notebook_bottom) for free storage

In [88]:

```
filename = "https://cf-courses-data.s3.us.cloud-object-storage.appdomain.cloud/IBMDevel
operSkillsNetwork-DA0101EN-SkillsNetwork/labs/Data%20files/auto.csv"
```

Python list **headers** containing name of headers

In [89]:

```
headers = ["symboling","normalized-losses","make","fuel-type","aspiration", "num-of-doo
rs","body-style",
         "drive-wheels","engine-location","wheel-base", "length","width","height","curb
-weight","engine-type",
         "num-of-cylinders", "engine-size","fuel-system","bore","stroke","compression-r
atio","horsepower",
         "peak-rpm","city-mpg","highway-mpg","price"]
print("headers\n",headers)
```

```
headers
 ['symboling', 'normalized-losses', 'make', 'fuel-type', 'aspiration', 'nu
m-of-doors', 'body-style', 'drive-wheels', 'engine-location', 'wheel-bas
e', 'length', 'width', 'height', 'curb-weight', 'engine-type', 'num-of-cyl
inders', 'engine-size', 'fuel-system', 'bore', 'stroke', 'compression-rati
o', 'horsepower', 'peak-rpm', 'city-mpg', 'highway-mpg', 'price']
```

Use the Pandas method **read_csv()** to load the data from the web address. Set the parameter "names" equal to the Python list "headers".

In [90]:

```
df = pd.read_csv(filename, names = headers)
```

Use the method **head()** to display the first five rows of the dataframe.

In [91]:

```
# To see what the data set looks like, we'll use the head() method.
df.head()
```

Out[91]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	?	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	?	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	?	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 26 columns

As we can see, several question marks appeared in the dataframe; those are missing values which may hinder our further analysis.
So, how do we identify all those missing values and deal with them?

How to work with missing data?

Steps for working with missing data:

1. dentify missing data
2. deal with missing data
3. correct data format

Identify and handle missing values

Identify missing values

Convert "?" to NaN

In the car dataset, missing data comes with the question mark "?". We replace "?" with NaN (Not a Number), which is Python's default missing value marker, for reasons of computational speed and convenience. Here we use the function:

```
.replace(A, B, inplace = True)
```

to replace A by B

In [92]:

```
import numpy as np

# replace "?" to NaN
df.replace("?", np.nan, inplace = True)
df.head(5)
```

Out[92]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	NaN	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	NaN	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	NaN	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 26 columns

Identify_missing_values

Evaluating for Missing Data

The missing values are converted to default. We use the following functions to identify these missing values. There are two methods to detect missing data:

1. **.isnull()**
2. **.notnull()**

The output is a boolean value indicating whether the value that is passed into the argument is in fact missing data.

In [93]:

```
missing_data = df.isnull()
#or
#missing_data = df.notnull()
missing_data.head(5)
```

Out[93]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wheel-base
0	False	True	False	False	False	False	False	False	False	False
1	False	True	False	False	False	False	False	False	False	False
2	False	True	False	False	False	False	False	False	False	False
3	False	False	False	False	False	False	False	False	False	False
4	False	False	False	False	False	False	False	False	False	False

5 rows × 26 columns

"True" stands for missing value, while "False" stands for not missing value.

Count missing values in each column

Using a for loop in Python, we can quickly figure out the number of missing values in each column. As mentioned above, "True" represents a missing value, "False" means the value is present in the dataset. In the body of the for loop the method ".value_counts()" counts the number of "True" values.

In [94]:

```
for column in missing_data.columns.values.tolist():
    print(column)
    print (missing_data[column].value_counts())
    print("")
# or you can summary the missing value by this function isnull().sum()
df.isnull().sum()
```

highway-mpg           0
price                 4
dtype: int64
```

Based on the summary above, each column has 205 rows of data, seven columns containing missing data:

1. "normalized-losses": 41 missing data
2. "num-of-doors": 2 missing data
3. "bore": 4 missing data
4. "stroke" : 4 missing data
5. "horsepower": 2 missing data
6. "peak-rpm": 2 missing data
7. "price": 4 missing data

Deal with missing data

How to deal with missing data?

1. drop data
   a. drop the whole row
   b. drop the whole column
2. replace data
   a. replace it by mean
   b. replace it by frequency
   c. replace it based on other functions

Whole columns should be dropped only if most entries in the column are empty. In our dataset, none of the columns are empty enough to drop entirely. We have some freedom in choosing which method to replace data; however, some methods may seem more reasonable than others. We will apply each method to many different columns:

Replace by mean:

- "normalized-losses": 41 missing data, replace them with mean
- "stroke": 4 missing data, replace them with mean
- "bore": 4 missing data, replace them with mean
- "horsepower": 2 missing data, replace them with mean
- "peak-rpm": 2 missing data, replace them with mean

Replace by frequency:

- "num-of-doors": 2 missing data, replace them with "four".
    - Reason: 84% sedans is four doors. Since four doors is most frequent, it is most likely to occur

Drop the whole row:

- "price": 4 missing data, simply delete the whole row
    - Reason: price is what we want to predict. Any data entry without price data cannot be used for prediction; therefore any row now without price data is not useful to us

Calculate the average of the column

In [95]:

```
avg_norm_loss = df["normalized-losses"].astype("float").mean(axis=0)
print("Average of normalized-losses:", avg_norm_loss)
```

```
Average of normalized-losses: 122.0
```

Replace "NaN" by mean value in "normalized-losses" column

In [96]:

```
df["normalized-losses"].replace(np.nan, avg_norm_loss, inplace=True)
```

Calculate the mean value for 'bore' column

In [97]:

```
avg_bore=df['bore'].astype('float').mean(axis=0)
print("Average of bore:", avg_bore)
```

```
Average of bore: 3.3297512437810943
```

Replace NaN by mean value

In [98]:

```
df["bore"].replace(np.nan, avg_bore, inplace=True)
```

Question #1:

According to the example above, replace NaN in "stroke" column by mean.

In [99]:

```
# Write your code below and press Shift+Enter to execute
# astype() function is added to convert the data type to the correct one (float), somet
imes there mistake in typing data type.
# sometimes it is INT or float, but then in the dataset they write it as object. so add
ing astype() is to make sure
# that the data type is in correct one
# if you are sure the datatype is correct, then you should not add astype()
avg_stroke = df["stroke"].astype(float).mean(axis=0)
print("Average of stroke is :", avg_stroke)
df["stroke"].replace(np.nan, avg_stroke, inplace = True)
```

```
Average of stroke is : 3.255422885572139
```

Click here for the solution

Calculate the mean value for the 'horsepower' column:

In [100]:

```
# astype() function is added to convert the data type to the correct one (float), somet
imes there mistake in typing data type.
# sometimes it is INT or float, but then in the dataset they write it as object. so add
ing astype() is to make sure
# that the data type is in correct one
# if you are sure the datatype is correct, then you should not add astype()
avg_horsepower = df['horsepower'].astype('float').mean(axis=0)
print("Average horsepower:", avg_horsepower)
```

```
Average horsepower: 104.25615763546799
```

Replace "NaN" by mean value:

In [101]:

```
df['horsepower'].replace(np.nan, avg_horsepower, inplace=True)
```

Calculate the mean value for 'peak-rpm' column:

In [102]:

```
# astype() function is added to convert the data type to the correct one (float), somet
imes there mistake in typing data type.
# sometimes it is INT or float, but then in the dataset they write it as object. so add
ing astype() is to make sure
# that the data type is in correct one
# if you are sure the datatype is correct, then you should not add astype()
avg_peakrpm=df['peak-rpm'].astype('float').mean(axis=0)
print("Average peak rpm:", avg_peakrpm)
```

```
Average peak rpm: 5125.369458128079
```

Replace NaN by mean value:

In [103]:

```
df['peak-rpm'].replace(np.nan, avg_peakrpm, inplace=True)
```

To see which values are present in a particular column, we can use the ".value_counts()" method:

In [104]:

```
df['num-of-doors'].value_counts()
```

Out[104]:

```
four    114
two      89
Name: num-of-doors, dtype: int64
```

We can see that four doors are the most common type. We can also use the ".idxmax()" method to calculate for us the most common type automatically:

In [105]:

```
df['num-of-doors'].value_counts().idxmax()
```

Out[105]:

```
'four'
```

The replacement procedure is very similar to what we have seen previously

In [106]:

```
#replace the missing 'num-of-doors' values by the most frequent
df["num-of-doors"].replace(np.nan, "four", inplace=True)
```

Finally, let's drop all rows that do not have price data:

In [107]:

```
# subset defines in which columns to look for missing values:
# simply drop whole row with NaN in "price" column
df.dropna(subset=["price"], axis=0, inplace=True)

# reset index, because we droped two rows
df.reset_index(drop=True, inplace=True)
```

In [108]:

```
df.head()
```

Out[108]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	122	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 26 columns

Good! Now, we obtain the dataset with no missing values.

Correct data format

We are almost there!

The last step in data cleaning is checking and making sure that all data is in the correct format (int, float, text or other).

In Pandas, we use

.dtype() to check the data type

.astype() to change the data type

Lets list the data types for each column

In [109]:

```
df.dtypes
```

Out[109]:

```
symboling              int64
normalized-losses     object
make                  object
fuel-type             object
aspiration            object
num-of-doors          object
body-style            object
drive-wheels          object
engine-location       object
wheel-base           float64
length               float64
width                float64
height               float64
curb-weight            int64
engine-type           object
num-of-cylinders      object
engine-size            int64
fuel-system           object
bore                  object
stroke                object
compression-ratio    float64
horsepower            object
peak-rpm              object
city-mpg               int64
highway-mpg            int64
price                 object
dtype: object
```

As we can see above, some columns are not of the correct data type. Numerical variables should have type 'float' or 'int', and variables with strings such as categories should have type 'object'. For example, 'bore' and 'stroke' variables are numerical values that describe the engines, so we should expect them to be of the type 'float' or 'int'; however, they are shown as type 'object'. We have to convert data types into a proper format for each column using the "astype()" method.

Convert data types to proper format

In [110]:

```
df[["bore", "stroke"]] = df[["bore", "stroke"]].astype("float")
df[["normalized-losses"]] = df[["normalized-losses"]].astype("int")
df[["price"]] = df[["price"]].astype("float")
df[["peak-rpm"]] = df[["peak-rpm"]].astype("float")
```

Let us list the columns after the conversion

In [111]:

```
df.dtypes
```

Out[111]:

```
symboling              int64
normalized-losses      int64
make                  object
fuel-type             object
aspiration            object
num-of-doors          object
body-style            object
drive-wheels          object
engine-location       object
wheel-base           float64
length               float64
width                float64
height               float64
curb-weight            int64
engine-type           object
num-of-cylinders      object
engine-size            int64
fuel-system           object
bore                 float64
stroke               float64
compression-ratio    float64
horsepower            object
peak-rpm             float64
city-mpg               int64
highway-mpg            int64
price                float64
dtype: object
```

Wonderful!

Now, we finally obtain the cleaned dataset with no missing values and all data in its proper format.

Data Standardization

Data is usually collected from different agencies with different formats. (Data Standardization is also a term for a particular type of data normalization, where we subtract the mean and divide by the standard deviation)

What is Standardization?

Standardization is the process of transforming data into a common format which allows the researcher to make the meaningful comparison.

Example

Transform mpg to L/100km:

In our dataset, the fuel consumption columns "city-mpg" and "highway-mpg" are represented by mpg (miles per gallon) unit. Assume we are developing an application in a country that accept the fuel consumption with L/100km standard

We will need to apply **data transformation** to transform mpg into L/100km?

The formula for unit conversion is

L/100km = 235 / mpg

We can do many mathematical operations directly in Pandas.

In [112]:

```
df.head()
```

Out[112]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	122	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 26 columns

In [113]:

```
# Convert mpg to L/100km by mathematical operation (235 divided by mpg)
df['city-L/100km'] = 235/df["city-mpg"]

# check your transformed data
df.head()
```

Out[113]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	122	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 27 columns

Question #2:

According to the example above, transform mpg to L/100km in the column of "highway-mpg", and change the name of column to "highway-L/100km".

In [114]:

```
# Write your code below and press Shift+Enter to execute
# transform mpg to L/100km by mathematical operation (235 divided by mpg)
df["highway-mpg"] = 235/df["highway-mpg"]

# rename column name from "highway-mpg" to "highway-L/100km"
df.rename(columns={'highway-mpg':'highway-L/100km'}, inplace=True)

# check your transformed data
df.head()
```

Out[114]:

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wh b
0	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
1	3	122	alfa-romero	gas	std	two	convertible	rwd	front	
2	1	122	alfa-romero	gas	std	two	hatchback	rwd	front	
3	2	164	audi	gas	std	four	sedan	fwd	front	
4	2	164	audi	gas	std	four	sedan	4wd	front	

5 rows × 27 columns

Click here for the solution

Data Normalization

Why normalization?

Normalization is the process of transforming values of several variables into a similar range. Typical normalizations include scaling the variable so the variable average is 0, scaling the variable so the variance is 1, or scaling variable so the variable values range from 0 to 1

Example

To demonstrate normalization, let's say we want to scale the columns "length", "width" and "height"

Target:would like to Normalize those variables so their value ranges from 0 to 1.

Approach: replace original value by (original value)/(maximum value)

In [115]:

```
# replace (original value) by (original value)/(maximum value)
df['length'] = df['length']/df['length'].max()
df['width'] = df['width']/df['width'].max()
```

Questiont #3:

According to the example above, normalize the column "height".

In [116]:

```
# Write your code below and press Shift+Enter to execute
df['height'] = df['height']/df['height'].max()
# show the scaled columns
df[["length","width","height"]].head()
```

Out[116]:

	length	width	height
0	0.811148	0.890278	0.816054
1	0.811148	0.890278	0.816054
2	0.822681	0.909722	0.876254
3	0.848630	0.919444	0.908027
4	0.848630	0.922222	0.908027

Click here for the solution

Here we can see, we've normalized "length", "width" and "height" in the range of [0,1].

Binning

Why binning?

Binning is a process of transforming continuous numerical variables into discrete categorical 'bins', for grouped analysis.

Example:

In our dataset, "horsepower" is a real valued variable ranging from 48 to 288, it has 57 unique values. What if we only care about the price difference between cars with high horsepower, medium horsepower, and little horsepower (3 types)? Can we rearrange them into three 'bins' to simplify analysis?

We will use the Pandas method 'cut' to segment the 'horsepower' column into 3 bins

Example of Binning Data In Pandas

Convert data to correct format

In [117]:

```
df["horsepower"]=df["horsepower"].astype(int, copy=True)
```

Lets plot the histogram of horspower, to see what the distribution of horsepower looks like.

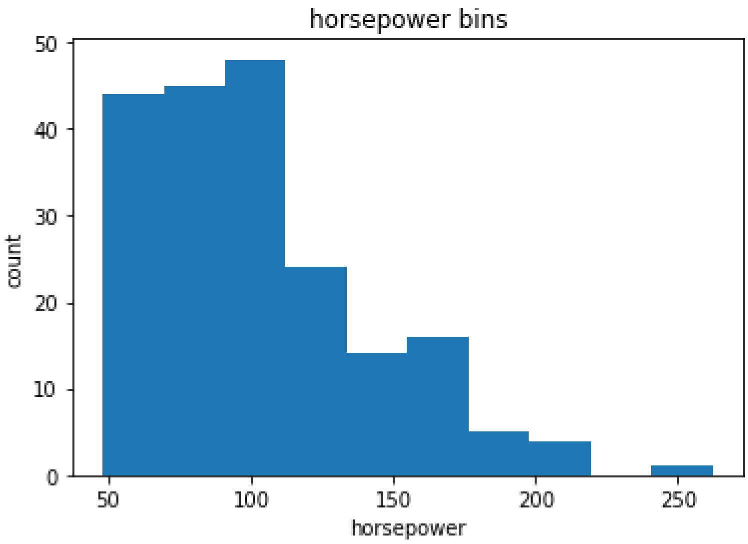
In [118]:

```
%matplotlib inline
import matplotlib as plt
from matplotlib import pyplot
plt.pyplot.hist(df["horsepower"])

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

Out[118]:

```
Text(0.5, 1.0, 'horsepower bins')
```



We would like 3 bins of equal size bandwidth so we use numpy's `linspace(start_value, end_value, numbers_generated` function.

Since we want to include the minimum value of horsepower we want to set start_value=min(df["horsepower"]).

Since we want to include the maximum value of horsepower we want to set end_value=max(df["horsepower"]).

Since we are building 3 bins of equal length, there should be 4 dividers, so numbers_generated=4.

We build a bin array, with a minimum value to a maximum value, with bandwidth calculated above. The bins will be values used to determine when one bin ends and another begins.

In [119]:

```
bins = np.linspace(min(df["horsepower"]), max(df["horsepower"]), 4)
bins
```

Out[119]:

```
array([ 48.        , 119.33333333, 190.66666667, 262.        ])
```

We set group names:

In [120]:

```
group_names = ['Low', 'Medium', 'High']
```

We apply the function "cut" the determine what each value of "df['horsepower']" belongs to.

In [121]:

```
df['horsepower-binned'] = pd.cut(df['horsepower'], bins, labels=group_names, include_lo
west=True )
df[['horsepower','horsepower-binned']].head(20)
```

Out[121]:

	horsepower	horsepower-binned
0	111	Low
1	111	Low
2	154	Medium
3	102	Low
4	115	Low
5	110	Low
6	110	Low
7	110	Low
8	140	Medium
9	101	Low
10	101	Low
11	121	Medium
12	121	Medium
13	121	Medium
14	182	Medium
15	182	Medium
16	182	Medium
17	48	Low
18	70	Low
19	70	Low

Lets see the number of vehicles in each bin.

In [122]:

```
df["horsepower-binned"].value_counts()
```

Out[122]:

```
Low       153
Medium     43
High        5
Name: horsepower-binned, dtype: int64
```

Lets plot the distribution of each bin.

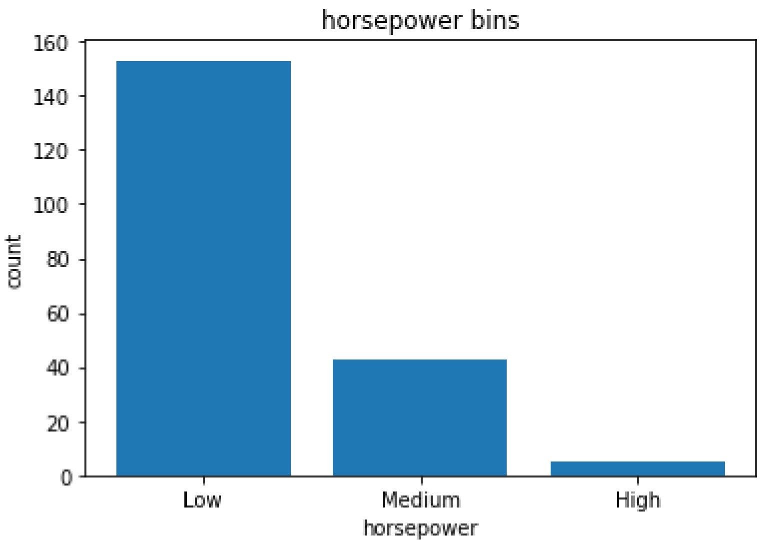
In [123]:

```
%matplotlib inline
import matplotlib as plt
from matplotlib import pyplot
pyplot.bar(group_names, df["horsepower-binned"].value_counts())

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

Out[123]:

```
Text(0.5, 1.0, 'horsepower bins')
```



Check the dataframe above carefully, you will find the last column provides the bins for "horsepower" with 3 categories ("Low","Medium" and "High").

We successfully narrow the intervals from 57 to 3!

Bins visualization

Normally, a histogram is used to visualize the distribution of bins we created above.

In [124]:

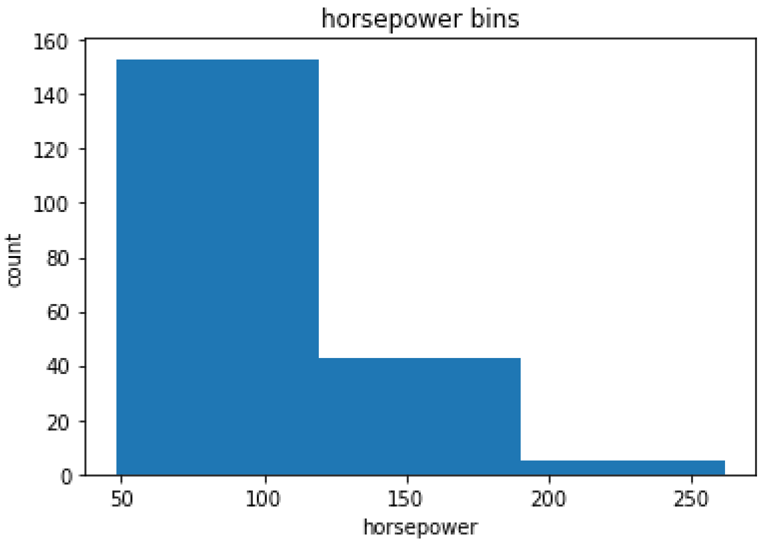
```
%matplotlib inline
import matplotlib as plt
from matplotlib import pyplot

# draw historgram of attribute "horsepower" with bins = 3
plt.pyplot.hist(df["horsepower"], bins = 3)

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

Out[124]:

```
Text(0.5, 1.0, 'horsepower bins')
```



The plot above shows the binning result for attribute "horsepower".

Indicator variable (or dummy variable)

What is an indicator variable?

An indicator variable (or dummy variable) is a numerical variable used to label categories. They are called 'dummies' because the numbers themselves don't have inherent meaning.

Why we use indicator variables?

So we can use categorical variables for regression analysis in the later modules.

Example

We see the column "fuel-type" has two unique values, "gas" or "diesel". Regression doesn't understand words, only numbers. To use this attribute in regression analysis, we convert "fuel-type" into indicator variables.

We will use the panda's method 'get_dummies' to assign numerical values to different categories of fuel type.

In [125]:

```
df.columns
```

Out[125]:

```
Index(['symboling', 'normalized-losses', 'make', 'fuel-type', 'aspiratio
n',
       'num-of-doors', 'body-style', 'drive-wheels', 'engine-location',
       'wheel-base', 'length', 'width', 'height', 'curb-weight', 'engine-t
ype',
       'num-of-cylinders', 'engine-size', 'fuel-system', 'bore', 'stroke',
       'compression-ratio', 'horsepower', 'peak-rpm', 'city-mpg',
       'highway-L/100km', 'price', 'city-L/100km', 'horsepower-binned'],
      dtype='object')
```

get indicator variables and assign it to data frame "dummy_variable_1"

In [126]:

```
dummy_variable_1 = pd.get_dummies(df["fuel-type"])
dummy_variable_1.head()
```

Out[126]:

	diesel	gas
0	0	1
1	0	1
2	0	1
3	0	1
4	0	1

change column names for clarity

In [127]:

```
dummy_variable_1.rename(columns={'gas':'fuel-type-gas', 'diesel':'fuel-type-diesel'}, i
nplace=True)
dummy_variable_1.head()
```

Out[127]:

	fuel-type-diesel	fuel-type-gas
0	0	1
1	0	1
2	0	1
3	0	1
4	0	1

In the dataframe, column fuel-type has a value for 'gas' and 'diesel'as 0s and 1s now.

In [128]:

```
# merge data frame "df" and "dummy_variable_1"
df = pd.concat([df, dummy_variable_1], axis=1)

# drop original column "fuel-type" from "df"
df.drop("fuel-type", axis = 1, inplace=True)
```

In [129]:

```
df.head()
```

Out[129]:

	symboling	normalized-losses	make	aspiration	num-of-doors	body-style	drive-wheels	engine-location	wheel-base
0	3	122	alfa-romero	std	two	convertible	rwd	front	88.6
1	3	122	alfa-romero	std	two	convertible	rwd	front	88.6
2	1	122	alfa-romero	std	two	hatchback	rwd	front	94.5
3	2	164	audi	std	four	sedan	fwd	front	99.8
4	2	164	audi	std	four	sedan	4wd	front	99.4

5 rows × 29 columns

The last two columns are now the indicator variable representation of the fuel-type variable. It's all 0s and 1s now.

Question #4:

As above, create indicator variable to the column of "aspiration"

In [130]:

```
# Write your code below and press Shift+Enter to execute
dummy_variable_2 = pd.get_dummies(df["aspiration"])
dummy_variable_2.head()
```

Out[130]:

	std	turbo
0	1	0
1	1	0
2	1	0
3	1	0
4	1	0

In [131]:

```
dummy_variable_2.rename(columns={'std':'aspiration-std', 'turbo':'aspiration-turbo'}, i
nplace=True)
dummy_variable_2.head()
```

Out[131]:

	aspiration-std	aspiration-turbo
0	1	0
1	1	0
2	1	0
3	1	0
4	1	0

Click here for the solution

Question #5:

Merge the new dataframe to the original dataframe then drop the column 'aspiration'

In [132]:

```
# merge data frame "df" and "dummy_variable_2"
df = pd.concat([df, dummy_variable_2], axis=1)

# drop original column "fuel-type" from "df"
df.drop("aspiration", axis = 1, inplace=True)
```

In [133]:

```
df.head()
```

Out[133]:

	symboling	normalized-losses	make	num-of-doors	body-style	drive-wheels	engine-location	wheel-base	length	
0	3	122	alfa-romero	two	convertible	rwd	front	88.6	0.811148	0.
1	3	122	alfa-romero	two	convertible	rwd	front	88.6	0.811148	0.
2	1	122	alfa-romero	two	hatchback	rwd	front	94.5	0.822681	0.
3	2	164	audi	four	sedan	fwd	front	99.8	0.848630	0.
4	2	164	audi	four	sedan	4wd	front	99.4	0.848630	0.

5 rows × 30 columns

Click here for the solution

Save the new csv

In [134]:

```
df.to_csv('clean_df.csv')
```

Thank you for completing this lab!
